

## Commitment

It allows one to commit to a chosen value while keeping it hidden to others.

However, it can be revealed at a later time when the one opens necessary parameter.

- Hiding; a given  $x$  and its commitment should be unrelatable.  
 $\Rightarrow$  should reveal no information about  $x$
- Binding; there is no way that different values can result in the same commitment.  
 $\Rightarrow$  cannot change the value after committing

cf.

- Encryption
- Hash function

## Pedersen Commitment [Ped92]

- $\text{Setup}(1^\lambda)$ ;
  - Choose a large prime  $q$  and  $p$  such that  $p = 2q + 1$
  - Choose  $g \leftarrow \mathbb{Z}_q^*$
  - Choose  $s \leftarrow \mathbb{Z}_q^*$  and compute  $h := g^s$
  - Output  $(p, q, g, h)$
- $\text{Com}(x)$ ;
  - Choose  $\gamma \leftarrow \mathbb{Z}_q^*$
  - Output  $g^x h^\gamma$
- $\text{Open}(\text{Com}(x), x, \gamma)$ ;
  - Check whether  $c$  is equal to  $g^x h^\gamma$  or not

### Note

- $\Sigma$ -Protocols: to prove knowledge of a committed value, equality of two committed values and so on.
- Since  $g^{x_1} h^{\gamma_1} \cdot g^{x_2} h^{\gamma_2} = g^{x_1+x_2} h^{\gamma_1+\gamma_2}$ ,

$$\text{Com}(x_1, \gamma_1) \cdot \text{Com}(x_2, \gamma_2) = \text{Com}(x_1 + x_2, \gamma_1 + \gamma_2)$$

- Linear relationships among committed values can be shown through Pedersen commitments.
  - One could show that  $y = ax + b$  for some public values  $a$  and  $b$ , given  $\text{Com}(x)$  and  $\text{Com}(y)$ .

### Example 1. ( $\Sigma$ -protocol for Pedersen Commitment)

Let  $p$  be a DL-secure prime and  $g, h \leftarrow \mathbb{Z}_p^*$ .

Prover and Verifier knows  $g, h$  and  $y = g^x h^\gamma = \text{Com}(x)$

Prover claims to know a committed value  $x$  and  $\gamma$ .

1. [Announcement]

- Choose  $s, t \leftarrow \mathbb{Z}_q^*$
- Compute  $a = g^s h^t$
- Send  $a$  to Verifier

2. [Challenge]

- Choose  $c \leftarrow \mathbb{Z}_q^*$
- Send  $c$  to Prover

3. [Response]

- Compute  $r_1 = cx + s$  and  $r_2 = c\gamma + t$
- Send  $r_1$  and  $r_2$  to Verifier

4. [Verification]

- If  $y^c \cdot a = g^{r_1} h^{r_2}$ , then Verifier accepts
- Otherwise, Verifier rejects

## Example 2.

Let  $p$  be a DL-secure prime and  $g, h \leftarrow \mathbb{Z}_p^*$ .

Prover and Verifier knows  $g, h$  and  $y_1 = g^{x_1} h^{\gamma_1} = \text{Com}(x_1)$  and  $y_2 = g^{x_2} h^{\gamma_2} = \text{Com}(x_2)$ .

Prover proves knowledge of  $x_1$  and  $x_2$  such that  $x_2 = \alpha x_1 + \beta$ , that is, proving knowledge of  $x$  such that

$$\{y_1 = \text{Com}(x_1) \wedge y_2 = y_1^\alpha g^\beta\}$$

1. [Announcement]

- Choose  $s_1, s_2, t_1, t_2 \leftarrow \mathbb{Z}_q^*$
- Compute  $a_1 = g^{s_1} h^{t_1}$  and  $a_2 = g^{s_2} h^{t_2}$
- Send  $a_1$  and  $a_2$  to Verifier

2. [Challenge]

- Choose  $c_1, c_2 \leftarrow \mathbb{Z}_q^*$
- Send  $c_1$  and  $c_2$  to Prover

3. [Response]

- Compute  $r_1 = c_1 x_1 + s_1, r_2 = c_1 \gamma_1 + t_1, r_3 = c_2 x_2 + s_2$  and  $r_4 = \alpha c_2 \gamma_1 + t_2$
- Send  $r_1, r_2, r_3$  and  $r_4$  to Verifier

4. [Verification]

- If  $y_1^{c_1} \cdot a_1 = g^{r_1} h^{r_2}$  and  $y_1^{c_2 \alpha} \cdot a_2 \cdot g^{c_2 \beta} = g^{r_3} h^{r_4}$ , then Verifier accepts
- Otherwise, Verifier rejects

## zkSNARKs and zkSTARKs

zero-knowledge of Succinct Non-interactive ARguments of Knowledgs

zero-knowledge of Scalable Transparent ARgument of Knowledges

	$\Sigma$ -Protocol	zkSNARKs	zkSTARKs
	no trusted setup	required a trusted setup	no trusted setup
Algebraic	short proof size	large proof size	large proof size
Non-Algebraic	large proof size	succinct proof size	larger than SNARKs
		verifiable computation	post-quantum

- $\Sigma$ -Protocol
  - zkBoo: [GMO16] @ USENIX'16,
  - Ligerio: [AHIV17] @ CCS'17
- zkSNARK
  - Pinocchio: [PGHR13] @ S&P'13
  - Geppetto: [CFH+15] @ S&P'15
- Hybrid
  - [AGM18] @ CRYPTO'18

## Privacy Problem in BTC

- Anonymity: *hiding identities* of sender and receiver
  - Monero uses a ring signature and a stealth address
  - ZCash uses a zero-knowledge proof
- Confidentiality: *hiding the amount* transferred
  - Monero uses a confidential transaction (CT)
    - every transaction amount is hidden using a commitment to the amount
  - ZCash uses a commitment and a public key encryption

In CT, a zero-knowledge for range proof is used.

1.  $\sum \text{input} \geq \sum \text{output}$
2. all transferred value  $\geq 0$

### Current Proposals for CT-ZKP

- [PBF+]: large proof size or required a trusted setup
- SNARKs: required a trusted setup
- STARKs: large range proof
- Bulletproof: [BBB+18] @ S&P'18
